

### FEATURES

- Wide supply voltage range: 6.0 V to 30.0 V
- Multiple inputs can monitor 3 to 6 cell voltages and 2 temperatures
- Adjustable threshold levels: overvoltage, undervoltage, overtemperature
- Alarm options: separate or shared alarms
- Extended temperature range performance  
 $-40^{\circ}\text{C} \leq T_A \leq +105^{\circ}\text{C}$
- Can be daisy-chained
- Internal reference
- Powered from battery stack
- LDO available to power isolator
- Qualified for automotive applications
- Extensive self-test feature aids in meeting ASIL/SIL requirements

### APPLICATIONS

- Lithium ion battery backup monitor and threshold detection
- Electric and hybrid electric vehicle
- Industrial vehicle
- Uninterruptible power supply
- Wind and solar

### GENERAL DESCRIPTION

The AD8280 is a hardware-only safety monitor for lithium ion battery stacks. The part has inputs to monitor six battery cells and two temperature sensors (either NTC or PTC thermistors). The part is designed to be daisy-chained with other AD8280 devices to monitor a stack of significantly more than six cells without the need for numerous isolators. Its output can be configured for an independent or shared alarm state.

The AD8280 functions independently from a primary monitor and contains its own reference and LDO, both of which are powered completely from the battery cell stack. The reference, in conjunction with external resistor dividers, is used to establish trip points for the overvoltages and undervoltages. Each cell channel contains programmable deglitching circuitry to prevent alarms from transient input levels.

The AD8280 also has two digital pins that can be used to select various combinations of inputs in the case where fewer than six cells are to be monitored. Most important, it has a self-test feature, making it suitable for high reliability applications, such as automotive hybrid electric vehicles or higher voltage industrial usage, such as uninterruptible power supplies. The AD8280 can function over a temperature range of  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$ .

## ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
VTOP to VBOTx	-0.3 V to +33 V
VIN0 to VBOTx	-0.3 V to LDO + 0.3 V
VIN1 Through VIN6 Voltage to VBOTx	-0.3 V to VTOP + 0.3 V
VTx to VBOTx	-0.3 V to LDO + 0.3 V
TESTI, ENBI to GNDx	-0.3 V to LDO + 0.3 V
DGTx, SELx, NPTC to GNDx	-0.3 V to LDO + 0.3 V
AVOUTxx to GNDx	-0.3 V to LDO + 0.3 V
TOP, BOT to VBOTx	-0.3 V to VTOP + 0.3 V

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 3. Thermal Resistance

Package Type	$\theta_{JA}$	$\theta_{JC}$	Unit
48-Lead LQFP (ST-48)	54	15	°C/W

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration

0891-1-002

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	VBOT2	Lowest Potential of Six-Cell Stack.
2	VBOT2S	Lowest Potential of Six-Cell Stack. Tie to VBOT2.
3	VBOT1S	Lowest Potential of Six-Cell Stack. Tie to VBOT1.
4	VBOT1	Lowest Potential of Six-Cell Stack.
5	VIN0	Input Voltage for Bottom of Cell 1.
6	VIN1	Input Voltage for Bottom of Cell 2/Top of Cell 1.
7	VIN2	Input Voltage for Bottom of Cell 3/Top of Cell 2.
8	VIN3	Input Voltage for Bottom of Cell 4/Top of Cell 3.
9	VIN4	Input Voltage for Bottom of Cell 5/Top of Cell 4.
10	VIN5	Input Voltage for Bottom of Cell 6/Top of Cell 5.
11	VIN6	Input Voltage for Top of Cell 6.
12	VTOP	Highest Potential of Six-Cell Stack.
13	VTOPS	Highest Potential of Six-Cell Stack. Tie to VTOP.
14	VT1	Temperature Input 1.
15	VT2	Temperature Input 2.
16	TESTI	Test Input.
17	AOUTOV	Alarm Current Output, Overvoltage. Used in daisy-chain configuration.
18	AOUTUV	Alarm Current Output, Undervoltage. Used in daisy-chain configuration.
19	AOUTOT	Alarm Current Output, Overtemperature. Used in daisy-chain configuration.
20	ENBI	Enable Input. When ENBI is logic high, the part is enabled; when ENBI is logic low, the part is disabled.
21	OV	Overvoltage Trip Point.
22	UV	Undervoltage Trip Point.
23	OT	Overtemperature Trip Point.
24	DGT2	Digital Select Pin 2. Used with DGT0 and DGT1 to select deglitch time (see Table 7).
25	AVOUTOT	Alarm Voltage Output, Overtemperature.
26	AVOUTUV	Alarm Voltage Output, Undervoltage.
27	AVOUTOV	Alarm Voltage Output, Overvoltage.

Pin No.	Mnemonic	Description
28	SEL1	Digital Select Pin 1. Used with SEL0 to select channels to be used (see Table 5).
29	SEL0	Digital Select Pin 0. Used with SEL1 to select channels to be used (see Table 5).
30	DGT1	Digital Select Pin 1. Used with DGT0 and DGT2 to select deglitch time (see Table 7).
31	DGT0	Digital Select Pin 0. Used with DGT1 and DGT2 to select deglitch time (see Table 7).
32	ALRMSEL	Selects three separate alarms or one shared alarm. When ALRMSEL is logic high, three separate alarms are selected; when ALRMSEL is logic low, one shared alarm is selected.
33	NPTC	Selects NTC or PTC thermistor for VTx inputs. When NPTC is tied to logic high (LDO pin), a PTC thermistor is selected; when NPTC is tied to logic low (VBOTx pin), an NTC thermistor is selected.
34	GND2	Ground. Tie to same potential as VBOT1 and VBOT2.
35	GND1	Ground. Tie to same potential as VBOT1 and VBOT2.
36	VCC	Supply Voltage. Tie to LDO.
37	VCCS	Supply Voltage Sense. Tie to LDO.
38	LDO	LDO Output. Tie to VCC, VCCS, and LDOS.
39	LDOS	LDO Output Sense. Tie to LDO.
40	FB	Feedback Pin. Tie to REF.
41	REF	Reference Output. Tie to FB.
42	ENBO	Enable Output.
43	AIINOT	Alarm Current Input, Overtemperature. Used in daisy-chain configuration.
44	AIINUV	Alarm Current Input, Undervoltage. Used in daisy-chain configuration.
45	AIINOV	Alarm Current Input, Overvoltage. Used in daisy-chain configuration.
46	TESTO	Test Output.
47	BOT	Used to identify part at lowest potential in daisy chain (see Table 6).
48	TOP	Used to identify part at highest potential in daisy chain (see Table 6).

## THEORY OF OPERATION

Figure 44 shows a block diagram of the AD8280. The AD8280 is a threshold monitor that can be used to monitor up to six cell voltages and two temperature voltages. The part can also be used in a daisy-chain configuration to monitor as many cells as required. The benefit of the daisy-chain configuration is that isolation is required to bring the alarm signal away from the high voltage environment on only the bottom part of the chain, reducing system cost and minimizing the board space required.

The cell and temperature voltage inputs are connected to the part using the VIN0 through VIN6 inputs and the VT1 and VT2 inputs, respectively. Because the six-cell stack voltage can be up to 30 V, the input voltages are level-shifted and referenced to the lowest potential (part ground or VBOTx) of the AD8280. These voltages are then input into window comparators and compared to trip points set by external resistor dividers.

If the cell or temperature voltage inputs exceed or fall below the selected trip points, an alarm, in the form of a digital voltage level, changes state at the voltage output (AVOUTxx) of the part. The alarm state also exists in the form of a current output (AIOUTxx) used to communicate to the other devices when multiple parts are used in a daisy-chain configuration.

The part contains programmable deglitching circuitry to ensure that transient voltages appearing at the cell inputs are ignored.

The part also contains its own LDO and reference. The LDO can be used to drive external components such as thermistors or isolators, whereas the reference can be used with the voltage dividers to establish the trip points.

The AD8280 has the following unique features and capabilities:

- Three, four, five, or six cells can be monitored.
- Negative or positive temperature coefficient thermistors can be used.
- Multiple parts can be configured in a daisy chain to monitor hundreds of cells. Information about the status of the alarms on the entire daisy chain, as well as input signals that enable the part and initiate self-test, are all communicated via the bottom, or master, part in the chain.
- Alarm outputs for overvoltage, undervoltage, and overtemperature status can be shared, with each output indicating the same status for any of the occurring alarm conditions, or the alarm outputs can function as separate entities with each indicating the status of the specific condition.
- An extensive self-test feature ensures that the internal components are functioning correctly. The self-test is initiated upon request to the TESTI pin.

Figure 44. Functional Block Diagram

## APPLICATIONS INFORMATION

### TYPICAL CONNECTIONS

Figure 45 is a block diagram of the AD8280 typical connections.

### CELL INPUTS

The battery stack of six cells should be connected to VIN0 through VIN6, with the highest potential connected to VIN6 and the lowest to VIN0. The connections should be made through a low-pass filter consisting of a 10 kΩ resistor and a 10 nF capacitor, as shown in Figure 45. The lowest potential of the six-cell stack should also be connected to VBOT1, VBOT1S, VBOT2, and VBOT2S as well, whereas the highest potential should be connected through a diode to VTOP and VTOPS. It is recommended that decoupling capacitors of 0.1 μF and 10 μF be used at the VTOP pin.

### TEMPERATURE INPUTS AND THERMISTOR SELECTION

VT1 and VT2 are voltage inputs and are designed to work with thermistors that are configured as resistor dividers, as shown in Figure 45. The voltage at the top of the thermistor divider should be the +5 V output of the LDO. The LDO pin can source more current than the REF pin and is better suited to drive the thermistor dividers.

If a voltage source other than that of the AD8280 LDO is used to drive the thermistor bridge ( $V_{TH}$ ), it is important that the VT1 and VT2 voltages be brought to 0 V when the AD8280 is disabled or powered down because the VT1 and VT2 inputs must be at 0 V when the LDO is also at 0 V.

- NOTES
- PART IS CONFIGURED AS FOLLOWS:  
MIDDLE PART IN DAISY CHAIN  
ALARMS ARE SHARED  
DEGLITCH TIME SET TO 0.0 SECONDS  
NTC THERMISTOR INPUTS  
6 CELL INPUTS

Figure 45. Typical Connections of the AD8280

08811-040

Also, if the resistor ( $R_{TOP}$ ) used in the top of the thermistor bridge circuit is less than 10 k $\Omega$ , another resistor ( $R_{IN}$ ) must be added in series to the input to the VTx pin (see Figure 46). The two resistors together must be greater than 10 k $\Omega$  ( $R_{TOP} + R_{IN} > 10\text{ k}\Omega$ ). This configuration is required only if  $V_{TH}$  is not the AD8280 LDO.

Figure 46. Input Configuration for VTx When Not Using the LDO for  $V_{TH}$

The part can work with both negative temperature coefficient (NTC) and positive temperature coefficient (PTC) thermistors. For NTC, the NPTC pin should be tied to logic low (VBOTx pin); for PTC, the NPTC pin should be tied to logic high (LDO pin). If the part is set to NTC mode, the OT alarm is tripped when the voltages at VT1 and VT2 drop below the trip point. If the part is set to PTC mode, the OT alarm is tripped when the voltages at VT1 and VT2 rise above the trip point.

## NUMBER OF CELLS SELECTION

The part can be configured to work with three, four, five, or six cells. Table 5 describes how to program the SEL0 and SEL1 pins to determine the number of cells being monitored. A logic low represents VBOTx, and a logic high represents the LDO output voltage. Figure 47 through Figure 49 show how to connect the cells to the part in a five-cell, four-cell, or three-cell application.

Table 5. SELx Pin Programming

Number of Cells Used	SEL0	SEL1
6 cells	0	0
5 cells (VIN5 shorted)	0	1
4 cells (VIN4 and VIN5 shorted)	1	0
3 cells (VIN3, VIN4, and VIN5 shorted)	1	1

Figure 47. Five-Cell Connections for the AD8280

Figure 48. Four-Cell Connections for the AD8280

Figure 49. Three-Cell Connections for the AD8280

## THRESHOLD INPUTS

The thresholds (or trip points) are set externally with a voltage divider providing maximum flexibility. The desired trip point voltage is connected to the following pins: OV (overvoltage trip point), UV (undervoltage trip point), and OT (overtemperature trip point). The +5 V output of either the reference (REF) or the LDO can be used as the top voltage of the divider. However, because the reference output is more accurate than the LDO output, the reference output is better suited to power the trip point setting dividers. If the thermistor dividers used for temperature sensing are driven from the LDO output, it is recommended that the LDO be used to drive the OT trip point divider as well for better temperature drift performance.

Decoupling capacitors (0.1  $\mu\text{F}$ ) should be used with the bottom leg of each divider in addition to a 2.2  $\mu\text{F}$  capacitor at the REF output, as shown in Figure 45.

The REF pin should be loaded with no more than 25 k $\Omega$  of resistance. Therefore, when using REF to drive three voltage dividers (OV, UV, and OT), it is recommended that the resistance of each divider total at least 75 k $\Omega$ . If driving only two dividers (OV and UV) with the reference, each divider should total no less than 50 k $\Omega$ .

## TOP AND BOTTOM PART DESIGNATION

When configured in a daisy chain, the AD8280 operates differently, depending on where it is in the chain: top part (highest potential), middle part, or bottom part (lowest potential). The TOP and BOT pins are used to designate the location of each part in the daisy chain. Table 6 is the logic table for identifying the location of the part in the daisy chain or, when not used in a daisy chain, identifying it as a single (standalone) part.

The logic high and logic low for the TOP and BOT pins are different from those of the other logic pins of the AD8280. The TOP and BOT pins are referenced to VTOP (logic high) and VBOTx (logic low), respectively.

**Table 6. Designation of the AD8280 in Daisy-Chain and Standalone Configurations**

Desired Condition	TOP <sup>1</sup>	BOT <sup>1</sup>
Middle part (middle potential part)	0	0
Bottom part (lowest potential part)	0	1
Top part (highest potential part)	1	0
Single part (highest and lowest potential part)	1	1

<sup>1</sup> For the TOP and BOT pins only, Logic 1 is VTOP and Logic 0 is VBOTx.

### Bottom Part in Daisy-Chain Configuration

The bottom part in a daisy-chain configuration is the master part and accepts voltage inputs into the ENBI and TESTI pins. The AIINOV, AIINUV, and AIINOT pins of the bottom part are connected to the AIOUTOV, AIOUTUV, and AIOUTOT pins, respectively, of the next higher potential part in the daisy chain. The AIOUTOV, AIOUTUV, and AIOUTOT pins of the bottom part can be left floating, or they can be tied to part ground (VBOTx).

### Middle Part in Daisy-Chain Configuration

When the AD8280 is designated as a middle part, the AIINOV, AIINUV, AIINOT, ENBO, and TESTO pins are connected to the AIOUTOV, AIOUTUV, AIOUTOT, ENBI, and TESTI pins, respectively, of the AD8280 above it.

### Top Part in Daisy-Chain Configuration

When the AD8280 is designated as a top part, the AIINOV, AIINUV, AIINOT, ENBO, and TESTO pins can be left floating, or they can be tied to VTOP.

### Standalone Part

When the AD8280 is designated as a single part (used as a standalone part), the AIOUTOV, AIOUTUV, and AIOUTOT pins can be left floating, or they can be tied to part ground (VBOTx). The AIINOV, AIINUV, AIINOT, ENBO, and TESTO pins can be left floating or tied to VTOP. The AD8280 accepts voltage inputs into the ENBI and TESTI pins.

### Alarm Signals in Daisy-Chain Configuration

Regardless of the part designation, the alarm signals are available as voltage outputs on any part in the chain on the AVOUTOV, AVOUTUV, and AVOUTOT pins. These signals

indicate the status of the part where the voltage alarms are monitored, as well as the status of the parts above it in the daisy chain. Make sure to use isolators to bring those signals outside the high voltage battery environment.

## TYPICAL DAISY-CHAIN CONNECTIONS

Figure 50 shows the typical connections for configuring the part in a daisy chain.

## SHARED OR SEPARATE ALARMS

The AD8280 can be configured for three separate alarms or for one shared alarm. Tying the ALRMSEL pin to a 5 V logic high forces the part into separate alarm mode. In this mode, each alarm trips only for its designated monitoring function. That is, the OV alarm trips only if an overvoltage condition exists at any of the cell inputs, the UV alarm trips only if an undervoltage condition exists at any of the cell inputs, and the OT alarm trips only if an overtemperature condition exists at either of the temperature inputs.

In shared alarm mode, any of the three conditions—overvoltage, undervoltage, or overtemperature—trips the alarm on all three signal chains. In shared mode, it is necessary to monitor only one alarm because all three contain the same signal.

## DEGLITCHING OPTIONS

The deglitching circuitry is available so that the part is immune to transients occurring at the cell inputs. If a transient voltage of a high or low enough level to trip an alarm occurs at the input to the part, the alarm state does not occur if the transient voltage is present for less than the selected deglitch time.

The DGT0, DGT1, and DGT2 pins are used to establish the deglitch time. Table 7 shows the options available and the corresponding logic levels to use when setting the deglitch time with the DGT0, DGT1, and DGT2 pins.

**Table 7. Fault Detection Time Pin Programming**

Deglitch Time	DGT0	DGT1	DGT2
0.0 sec	0	0	0
0.1 sec	0	0	1
0.8 sec	0	1	0
1.6 sec	0	1	1
3.2 sec	1	0	0
6.4 sec	1	0	1
12.8 sec	1	1	0

Do not tie all three deglitching pins (DGT0, DGT1, and DGT2) to logic high (111); this setting is used only during the testing of the part at the factory.

Setting the deglitch time to 0.0 sec (000) allows the use of an external deglitching circuit, if desired. Additionally, when the deglitch time is set to 0.0 sec, the time required to ensure that the part has completed its self-test is significantly reduced (see the Self-Test section). The DGTx pins should be tied to a fixed logic level and not toggled or changed during operation of the AD8280.

Figure 50. Typical Daisy-Chain Connections

08911-044

## ENABLING AND DISABLING THE AD8280

The AD8280 can be disabled or put into a standby mode by bringing the ENBI pin to logic low, lowering the quiescent current of the AD8280 from a maximum of 2.0 mA to 1.0  $\mu$ A and dropping the LDO and reference output to 0 V. Bringing the ENBI pin to a logic high takes the part out of standby mode and enables it.

When the AD8280 is used in a daisy-chain configuration, the enable/disable signal is a voltage logic level that is sent to the part designated as the bottom part (the bottom part monitors the lowest voltage cells). The bottom part transfers the enable/disable signal up the daisy chain via a current out of the ENBO pin and into the ENBI pin of the next higher part in the daisy chain. All the parts in the daisy chain are enabled by sending a logic high to the ENBI pin of the bottom, or master, part. All the parts in the daisy chain are disabled by sending a logic low to the ENBI pin of the bottom part.

## ALARM OUTPUT

The alarm status of the AD8280 appears as a voltage logic level at the AVOUTOV, AVOUTUV, and AVOUTOT pins. When the AD8280 is in a daisy-chain configuration, the alarm status is passed from the AIOU<sub>Txx</sub> pins of one part to the AIIN<sub>xx</sub> pins of the next lower potential part in the daisy chain. Figure 51 shows the output state when the part is in an unalarmed (logic low) or alarmed (logic high) state.

If the AD8280 is configured for the shared alarm mode, the status of all three voltage output pins (AVOU<sub>Txx</sub>) is the same. In shared alarm mode, the unused pins can be left floating, they can be tied to ground through a high resistance to limit the current draw, or they can be tied together.

## SELF-TEST

The AD8280 has the unique capability of extensively testing its internal components to ensure that they are functioning correctly. This feature is very important to the designer who is concerned with meeting the difficult safety integrity level guidelines of IEC 61508 or ISO 26262.

The part produces internal fault conditions and compares the results to what is expected. The status of the alarm signals is interrupted during the self-test, and the pass/fail status of the self-test is communicated via the alarm status signal pins (AVOU<sub>Txx</sub> and AIOU<sub>Txx</sub>).

Because the AD8280 uses an internal reference to perform its self-test, the self-test detects open circuits and short circuits at the threshold pins, as well.

See Figure 51 for a timing diagram and Figure 52 for timing definitions related to the self-test feature.

To initiate a self-test, the TESTI pin is prompted with a rising edge from a 5 V logic level pulse (test pulse). The pulse applied at TESTI must stay high for a minimum time ( $t_{ST\ min}$ ). Following the rising edge of the pulse to initiate the self-test, the alarm status for any AVOU<sub>Txx</sub> or AIOU<sub>Txx</sub> pin goes into a logic high status while the part performs its internal self-test. After sufficient time to perform the test has elapsed and assuming that the part passes self-test, the alarm status reverts to the unalarmed state, a logic low. If the part fails self-test, the alarm remains in a logic high state when the falling edge of the test pulse applied at TESTI occurs.

The minimum  $t_{ST}$  is dependent on the status of the DGT<sub>x</sub> pins. If all three DGT<sub>x</sub> pins are tied to a logic low, the self-test ignores the deglitch function of the part and completes the self-test in a shorter time (50 ms max). When at least one DGT<sub>x</sub> pin is set to logic high, the AD8280 defaults to the minimum deglitch time of 100 ms during the self-test. Because the self-test includes multiple layers and passes, this minimum time is specified as 700 ms. Therefore, if a faster self-test is required, the user should set the internal deglitch time to 0.0 sec and use an external deglitch circuit if deglitch is required.

## Self-Test in Daisy-Chain Configuration

The self-test can also be used when multiple AD8280 parts are configured in a daisy chain. The test pulse is applied to the TESTI pin of the bottom part as a voltage and then travels up the chain as a current. The self-test for each part is started as soon as the part sees the rising edge of the test pulse, virtually simultaneously. When the highest part in the chain passes its self-test, it sends that information to the next lower part in the daisy chain. Even if that part has already completed its self-test, it cannot pass its own result on to the next part in the daisy chain until it receives the pass signal from the part above it.

This process continues with each part lower down the chain. Therefore, when a pass signal appears at the bottom part in the daisy chain, it indicates that every part in the daisy chain passed the self-test. If any part in the chain fails the self-test, the part below the failing part never receives a pass signal, and, subsequently, the bottom part never receives a pass signal either. Therefore, regardless of whether the bottom part passes self-test, the AVOU<sub>Txx</sub> signals at the bottom part never change state from the logic high that occurred when the self-test was initiated, and the user will know that there is a failed part in the chain.

### Self-Test and Alarm Conditions

If an alarm occurs just prior to or just after the self-test pulse is initiated, the alarm causes the self-test to fail. The time span for this condition depends on the deglitch time.

- Deglitch time = 0.0 sec. The part fails self-test if an alarm occurs in the time period from 20 ms before the leading edge of the self-test pulse to 20 ms after the leading edge of the self-test pulse.
- Deglitch time > 0.0 sec. The part fails self-test if an alarm occurs in the time period from 120 ms before the leading edge of the self-test pulse to 120 ms after the leading edge of the self-test pulse.

Therefore, in the unusual circumstance that the part fails self-test and there is an alarm condition state after the self-test, it is recommended that the user retest the part to ensure that an alarm did not occur just prior to or just after initiating the self-test.

The self-test works when the part is in the shared alarm mode or in the separate alarm mode. When the part is in the separate alarm mode, the self-test status on an output pertains only to that portion of the internal circuit relevant to the condition being monitored: overvoltage, undervoltage, or overtemperature.

### Self-Test Timing and Monitoring Strategy

When monitoring the signals for self-test on the AD8280, note the following items:

- After initiating a self-test of the AD8280 with a rising edge on the TESTI pin, the alarm appearing at the AVOUTxx pin remains valid up to  $t_{RE\ max}$ .
- When the rising edge of the TESTI pulse occurs, the user should monitor the AVOUTxx pin to make sure that it is in the high state after the  $t_{RE\ max}$  time has elapsed.
- After the  $t_{ST\ max}$  time has elapsed, the user can verify that the AVOUTxx pin has changed to the low state, indicating that the part or parts passed the self-test. The user must also ensure that the minimum length of the TESTI pulse is greater than  $t_{ST\ max}$ . The status of the self-test on the AVOUTxx pin is valid until  $t_{STV\ min}$  after the trailing edge of the TESTI pulse.
- The alarm state is valid again  $t_{FE\ max}$  after the trailing edge of the pulse.

**NOTES**

1.  $t_{RE}$  IS THE TIME FROM THE RISING EDGE OF THE TEST PULSE (TESTI) TO THE START OF THE SELF-TEST.
2.  $t_{ST}$  IS THE TIME FROM THE RISING EDGE OF THE TEST PULSE UNTIL THE PART COMPLETES ITS SELF-TEST (TEST PULSE MUST BE LONGER THAN  $t_{ST}$  MAX).
3.  $t_{STV}$  IS THE TIME FROM THE FALLING EDGE OF THE TEST PULSE THAT THE SELF-TEST INDICATION REMAINS VALID (LOW = PASS, HIGH = FAIL).
4.  $t_{FE}$  IS THE TIME FROM THE FALLING EDGE OF THE TEST PULSE UNTIL THE SELF-TEST DATA IS CLEARED AND THE ALARM DATA IS AGAIN VALID.

## PROTECTION COMPONENTS AND PULL-UP/ PULL-DOWN RESISTORS

As shown in Figure 45, several devices are added to provide protection in a high voltage environment. Zener Diode Z1 ensures that the six-cell stack voltage does not significantly exceed the maximum 30 V across the part. It is recommended that a 33 V rated Zener diode be used for Z1.

The user can also use diodes in the daisy-chain lines (anode to cathode from higher potential to lower potential) to protect the parts in the event that an open circuit appears on the battery connections, causing a high reverse voltage across the AD8280 (these diodes are not shown in Figure 45). The diodes should have a reverse voltage rating comparable to the highest voltage of the battery system.

If diodes are used in the daisy chain, it is also recommended that a diode be used between the top cell in the stack (anode) and VTOP (cathode) of the top part, as well as between VBOTx (anode) of each part and VTOP (cathode) of the next lowest potential part in the daisy chain.

Because there are no pull-up or pull-down resistors internal to the part, the user may want to pull down the TESTI pin of the bottom part through a 10 k $\Omega$  resistor to VBOTx (part ground). The addition of this resistor ensures that the part is not locked in self-test mode if the line opens. Also, the user may want to pull up the ENBI pin on the bottom part of a daisy chain so that if the line opens, the chain stays in the enabled (powered up) mode.

## EMI CONSIDERATIONS

To increase immunity to electromagnetic interference (EMI), use the following components and layout schemes (see Figure 50).

- Use a 22 pF capacitor on each of the daisy-chain lines.
- Route the daisy-chain lines on an inner PCB layer.
- Use ground planes (connected to VBOTx from the higher potential part) both over and under the daisy-chain lines to shield them.
- Route the connections from VBOTx to VTOP to best ensure a low impedance connection between them.
- Use ferrite beads on the VTOP lines as shown in Figure 50.
- Use 100 nF capacitors across each of the six-cell battery stacks.
- Place the AD8280 parts as close together as possible on the board to minimize the length of the daisy-chain lines.

## SYSTEM ACCURACY CALCULATION

When calculating system accuracy, there are four error sources to consider:

- Trip point error (see Table 1)
- Reference voltage error (see Table 1)
- Resistor tolerance
- Resistor temperature coefficient

### Sample Calculation

Following is a sample calculation for overvoltage accuracy. In this calculation, the following conditions are assumed:

- Resistors used in the external resistor divider to set the trip points are  $\pm 1\%$ , 100 ppm/ $^{\circ}\text{C}$  resistors.
- Temperature range is  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ .
- Desired overvoltage trip point is 4.0 V (resistor values selected should be 15 k $\Omega$  and 60 k $\Omega$ ).

The resulting sources of error are described in this section.

### Maximum Trip Point Error

The maximum trip point error is  $\pm 15$  mV.

### Maximum Reference Error

The maximum reference error is as follows:

$$(60/(60 + 15)) \times \pm 50 \text{ mV} = \pm 40 \text{ mV}$$

### Maximum Resistor Tolerance Error

The maximum resistor tolerance error depends on the values of the resistors. If one resistor is high and the other is low, the worst-case error is as follows:

$$(60.6/(60.6 + 14.85)) \times 5.00 \text{ V} = 4.016 \text{ V (error of +16 mV)}$$

$$(59.4/(59.4 + 15.15)) \times 5.00 \text{ V} = 3.984 \text{ V (error of -16 mV)}$$

In this sample calculation, the maximum resistor tolerance error is  $\pm 16$  mV.

### Maximum Temperature Coefficient Error

If one resistor drifts high and the other resistor drifts low, the worst-case error is as follows:

$$60 \text{ k}\Omega + (100 \text{ ppm}/^{\circ}\text{C} \times (25^{\circ}\text{C} - (-40^{\circ}\text{C})) \times 60 \text{ k}\Omega) = 60.39 \text{ k}\Omega$$

$$15 \text{ k}\Omega - (100 \text{ ppm}/^{\circ}\text{C} \times (25^{\circ}\text{C} - (-40^{\circ}\text{C})) \times 15 \text{ k}\Omega) = 14.9 \text{ k}\Omega$$

$$(60.39/(60.39 + 14.90)) \times 5.00 \text{ V} = 4.010 \text{ V (error of +10 mV)}$$

or

$$60 \text{ k}\Omega - (100 \text{ ppm}/^{\circ}\text{C} \times (25^{\circ}\text{C} - (-40^{\circ}\text{C})) \times 60 \text{ k}\Omega) = 59.61 \text{ k}\Omega$$

$$15 \text{ k}\Omega + (100 \text{ ppm}/^{\circ}\text{C} \times (25^{\circ}\text{C} - (-40^{\circ}\text{C})) \times 15 \text{ k}\Omega) = 15.1 \text{ k}\Omega$$

$$(59.61/(59.61 + 15.10)) \times 5.00 \text{ V} = 3.990 \text{ V (error of -10 mV)}$$

In this sample calculation, the maximum temperature coefficient error is  $\pm 10$  mV.

### Total System Accuracy

The system accuracy, or the sum of all the errors, is  $\pm 81$  mV. If the resistor pair coefficients are matched so that drift is in the same direction, that portion of the error can be ignored, and the total system accuracy would be  $\pm 71$  mV.
